

Walkthrough | AtliQ Commerce : Real Time Lane

- Events are produced from a Python script and published to the Kafka topic

```
Delivered to atliq.orders.events [partition 3] offset 870
Delivered to atliq.orders.events [partition 3] offset 871
Delivered to atliq.orders.events [partition 5] offset 858
Delivered to atliq.orders.events [partition 5] offset 859
Delivered to atliq.orders.events [partition 3] offset 872
```

- The topic is created in the Kafka cluster on Confluent, and the produced events can be viewed in the Messages section of the topic in the Confluent Kafka Console.

- The events from the Kafka topic are read using Databricks Structured Streaming. A dedicated checkpoint tracks the last processed event, and Delta tables are used to store raw data in the Bronze layer, cleaned data in the Silver layer, and analytics-ready data in the Gold layer.
- We run an Airflow DAG with three tasks: check data freshness, optimize Delta tables, and update the Gold analytics table. Data Freshness: Succeeds when event data from the past 2 hours is available; otherwise, it fails, causing the respective downstream task to fail as well.

Success:
